AB Callus of bell pepper (Capsicum annuum cv. California) was initiated from hypocotyl on MS [Murashige and Skoog's] medium supplemented with NAA (0.5 mg/litre) and BAP [benzyladenine] (0.2 mg/litre). For proliferation of callus, the hormone concentrations were reduced by 50%. Cell clumps approximately 1 mm in diameter were exposed to polyethylene glycol (PEG) at concentrations ranging from 10 to 100 g/litre for water stress tolerance. Upon incubation for 30 days, the cells, which showed tolerance of PEG, formed calluses. Selected calluses were further subcultured in a ***selective*** ***medium*** containing 100 g PEG/litre for 8 weeks and then transferred to normal MS medium for proliferation. The selected calluses transferred from the normal to the ***selective*** ***medium*** exhibited growth. However, variation in growth was observed, and the pattern was sigmoidal in both cell lines. Compared to the control, selected cells contained significantly higher levels of soluble proteins, total sugars, reducing sugar, and free amino acids. The water stress tolerant cells also revealed enhanced activities of malate dehydrogenase, alkaline invertase, NADP+ - isocitrate dehydrogenase [isocitrate dehydrogenase (NADP+)], aspartate aminotransferase, glutamate pyruvate transaminase [***alanine*** aminotransferase], and acid phosphatase.

AB CadA, the P1-type ATPase involved in Listeria monocytogenes resistance to Cd(2+), was expressed in Saccharomyces cerevisiae and did just the opposite to what was expected, as it strikingly decreased the Cd(2+) tolerance of these cells. Yeast cells expressing the non-functional mutant Asp(398)Ala could grow on ***selective*** ***medium*** containing up to 100 microM Cd(2+), whereas those expressing the functional protein could not grow in the presence of 1 microM Cd(2+). The CadA-GFP fusion protein was localized in the endoplasmic reticulum membrane, suggesting that yeast hyper-sensitivity was due to Cd(2+) accumulation in the reticulum lumen. CadA is also known to transport Zn(2+), but Zn(2+) did not protect the cells against Cd(2+) poisoning. In the presence of 10 microM Cd(2+), transformed yeasts survived by rapid loss of their expression vector.

AB Bacteria were isolated from animal manure, soil and water samples on a ***selective*** ***medium*** devoid of amino acids. All the strains were found Gram-positive possessing in general rod shaped morphology accompanied with cocci cells except one strain which manifested pure coccus nature. Twenty percent of isolates produced only one amino acid. Of the remaining 5, 35 and 40% isolates produced four, three and two amino acids, respectively. The bacterial strains producing extracellular amino acid of one kind, gave rise to ***alanine*** , glycine and glutamic acid. Of the twenty bacterial isolates reported here four were optimized for growth and it was found that the isolates MRL-AA-4, MRL-AA-9 and MRL-AA-15 gave maximum production at 24 hours sampling period, while the strain MRL-AA-13 indicated highest yield of extracellular amino acids after 40 hours of incubation. These strains were found positive for catalase, motility and Voges-Proskauer tests, while they gave negative reactions for citrate utilization and MacConkey agar tests.

AB Mutations in the ligand-binding domain of the human androgen receptor (AR) figure among the ways used by prostate adenocarcinoma (PCa) cells to escape androgen dependence. These mutations may broaden the specificity and/or affinity of the AR to other hormones, resulting in inappropriate receptor activation and thus affecting the PCa response to physiol. stimuli and hormonal therapies. In order to clarify the impact of these mutations on disease progression and treatment, we have developed a yeast-based functional assay that allows the detection of mutant ARs and the anal. of their transactivation capacities in response to different ligands. AR cDNA was directly cloned into an expression vector in a yeast strain that carries a reporter gene (ADE2) linked to an androgen-dependent promoter. The expression of the ADE2 gene and consequently the yeast cell growth in a ***selective*** ***medium*** depleted in adenine depends on the specificity of the AR for the ligand added to the medium. By analyzing the transactivation capacities of different AR mols. in response to a broad range of steroid and non-steroid ligands, we have demonstrated that this assay can discriminate among wild-type AR, T877A. C685Y and L701H mutant ARs and that at least 1% of mutant ARs could be detected when mutant and wild-type ARs were mixed at the cDNA level. The data presented here show that this simple AR assay is convenient for the routine detection of mutant ARs in PCa and is also suitable to evaluate the antagonist activities of anti-androgen mols.

AB In order to screen for new microbial D-amino acid oxidase activities a selective and sensitive peroxidase/o-dianisidine assay, detecting the formation of hydrogen peroxide was developed. Catalase, which coexists with oxidases in the peroxisomes or the microsomes and, which competes with peroxidase for hydrogen peroxide, was completely inhibited by o-dianisidine up to a catalase activity of 500 nkat ml-1. Thus, using the peroxidase/o-dianisidine assay and employing crude extracts of microoganisms in a microplate reader, a detection sensitivity for oxidase activity of 0.6 nkat ml-1 was obtained. Wild type colonies which were grown on a ***selective*** ***medium*** containing D- ***alanine*** as carbon, energy and nitrogen source were examined for D-amino acid oxidase activity by the peroxidase/o-dianisidine assay. The oxidase positive colonies possessing an apparent oxidase activity > 2 nkat g dry biomass-1 were isolated. Among them three new D-amino acid oxidase-producers were found and identified as Fusarium oxysporum, Verticilium lutealbum and Candida parapsilosis. The best new D-amino oxidase producer was the fungus F. oxysporum with a D-amino acid oxidase activity of about 900 nkat g dry biomass-1 or 21 nkat mg protein-1. With regard to the use as a biocatalytic tool in biotechnology the substrate specificities of the three new D-amino acid oxidases were compared with those of the known D-amino acid oxidases from Trigonopsis variabilis, Rhodotorula gracilis and pig kidney under the same conditions. All six D-amino acid oxidases accepted the D-enantiomers of ***alanine*** , valine, leucine, proline, phenylalanine, serine and glutamine as substrates and, except for the D-amino acid oxidase from V. luteoalbum, D-tryptophane, D-tyrosine, D-arginine and D-histidine were accepted as well. The relative highest activities (>95%) were measured versus D- ***alanine*** (C. parapsilosis, F. oxysporum, T. variabilis), D-methionine (V. luteoalbum, R. gracilis), D-valine (T. variabilis, R. gracilis) and D-proline (pig kidney). The D-amino oxidases from F. oxysporum and V. luteoalbum were able to react with the industrially important substrate cephalosporin C although the D-amino acid oxidase from T. variabilis was at least about 20-fold more active with this substrate. As the results of our studies, a reliable oxidase assay was developed, allowing high throughput screening in a microplate reader. Furthermore, three new microbial D-amino acid oxidase-producers with interesting broad substrate specificities were introduced in the field of biotechnology.
AB. . . a detection sensitivity for oxidase activity of 0.6 nkat ml-1 was obtained. AB Nuclei isolated from metalaxyl-resistant (MR) protoplasts of Phytophthora parasitica were transferred into chloroneb-resistant (CnR) protoplasts of Phytophthora capsici and vice versa, with an average success rate of 2.6 x 10(-4) (protoplasts with donor nuclei/regenerated protoplasts), using a ***selective*** ***medium*** containing only the fungicide tolerated by the nuclear donor. No colonies appeared when self-fusion products of donor nuclei or recipient protoplasts were exposed to the ***selective*** ***medium*** . Colonies produced by the nuclear transfer formed sectors commonly, and differed from the parental types in appearance. All the zoospores produced by the nuclear hybrids were of normal size, and one-fifth of them contained both MR and CnR genes. Since zoospores are mostly uninucleate, these results indicated the occurrence of chromosome re-assortment or mitotic crossing-over following the production of transitory tetraploids, followed by diploidization during zoosporogenesis, thus suggesting the completion of events leading to a parasexual cycle. Hyphal fragment cultures from a nuclear hybrid tested showed considerable variation in growth rate, mycelial morphology, and level of resistance to metalaxyl, indicating uneven distribution and continuous segregation of different types of nuclei in mycelia during vegetative growth.

AB A strategy has been developed to express and purify a recombinant, nonfunctional axial-ligand mutant of iso-1-cytochrome c (Met-80 .fwdarw. Ala) in Saccharomyces cerevisiae in quantities necessary for extensive biophys. characterization. It involves coexpressing in the same plasmid (YEp213) the nonfunctional gene with a functional gene copy for complementation in a ***selective*** ***medium*** . The functional gene encodes a product with an engineered metal-chelating dihistidine site (His-39 and Leu-58 .fwdarw. His) that enables efficient sepn. of the two isoforms by immobilized metal-affinity chromatog. The purified Met-80 .fwdarw. Ala protein possesses a binding site for dioxygen and other exogenous ligands. Absorption spectra of several derivs. of this mutant show striking similarities to those of corresponding derivs. of horseradish peroxidase, myoglobin, and cytochrome P 450. The use of a dual-gene vector for cytochrome c expression together with metal-affinity sepn. opens the way for the engineering of variants with dramatically altered structural and catalytic properties.

AB A lysogenizing phage, .lambda. dilv-lac11, was constructed to carry an ilvD-lac operon fusion. Expression from the phage of the ilvE and lacZ genes is controlled by an intact ilv control region also carried by this phage. Two spontaneous mutants of .lambda. dilv-lac11 that have high-level constitutive expression of the ilv-lac fusion operon were isolated by growth on a .beta.-chloroalanine ***selective*** ***medium*** . The mutants were shown by nucleotide sequence determination to contain large deletions (.DELTA.2216, .apprx. 1.6 kilobases: .DELTA.2219, .apprx. 1.9 kilobases), which in both cases remove the proposed ilv attenuator terminator. The rest of the ilv leader and promoter region DNA remains intact in these mutants. Deletion 2216

removed part of the downstream ilvG gene. .DELTA.2219 extended through the entire ilvG gene into the ilvGE intercistronic region. A possible mechanism of deletion formation is discussed.

AB. . . of .lambda. dilv-lac11 that have high-level constitutive expression of the ilv-lac fusion operon were isolated by growth on a .beta.-chloroalanine ***selective*** ***medium*** . AB Antimetabolite analogs of essential amino acids are useful as selective agents for isolation of regulatory mutants of cyanobacteria, although striking microbiological differences from other widely used eubacterial systems were observed. Regulatory mutants shown to overproduce and excrete tryptophan, phenylalanine, tyrosine, methionine or arginine were isolated from 4 cyanobacteria: Anabaena sp. 29151, Synechococcus sp. 602, Synechococcus sp. AN Tx20 and Synechocystis sp. 29108. Surprisingly, regulatory-mutant colonies did not support a halo of cross-fed wild-type growth on ***selective*** ***medium*** . Since regulatory mutants were shown to excrete substantial levels of amino acids, it was deduced that poor cross-feeding must reflect a generally low nutritional responsiveness of the cyanobacterial background. Regulatory-mutant cells of cyanobacteria dispersed among wild-type populations of Bacillus subtilis did produce halo colonies on solid analog-containing medium. Cross-feeding between one cyanobacterial pair (a phenylalanine excretor and a phenylalanine auxotroph) was successfully demonstrated in the absence of the analog under conditions in which relatively large masses of each cell population type were spread near one another on agar plates. These results suggest that amino acid excreted by regulatory mutants of cyanobacteria on analog-containing ***selective*** ***medium*** is transported into nearby wild-type cells too inefficiently to overcome the antimetabolite effects of the analog, thereby failing to generate halos of phsyiologically resistant background cells. Consistent with this interpretation was the finding that the pheA1 auxotroph from Synechococcus sp. 602 exhibited a linearly proportional dependence of growth rate upon exogenous concentration of L-phenylalanine (below 20 .mu.M). Wild-type B. subtilis serves as a convenient and sensitive test lawn for screening obvious regulatory mutants for among collections of analog-resistant cyanobacterial mutants. Appropriate B. subtilis auxotrophs can be used as convenient indicator strains for the identification of regulatory mutants in cyanobacteria through the observation of syntrophic growth responses.

AB. . . sp. AN Tx20 and Synechocystis sp. 29108. Surprisingly, regulatory-mutant colonies did not support a halo of cross-fed wild-type growth on ***selective*** ***medium*** . Since regulatory mutants were shown to excrete substantial levels of amino acids, it was deduced that poor cross-feeding must reflect. . . near one another on agar plates. These results suggest that amino acid excreted by regulatory mutants of cyanobacteria on analog-containing ***selective*** ***medium*** is transported into nearby wild-type cells too inefficiently to overcome the antimetabolite effects of the analog, thereby failing to generate. . .

AB An attempt was made to develop a selective isolation medium for C. sporogenes and related organisms based on the ability of these organisms to obtain their energy for growth by means of coupled oxidation-reduction reactions between appropriate pairs of amino acids (Stickland reaction). Using a semi-defined basal medium containing various combinations of amino acids, it was found that C. sporogenes utilized a wider range of amino acid pairs than strains of 5 other species of clostridia known to carry out a Stickland-type fermentation. With ***alanine*** and proline as the principal energy sources and the medium solidified with agar, reference strains of C. sporogenes and proteolytic C. botulinum types A, B and F could be recovered almost quantitatively, with or without prior heating at 80.degree. C for 10 min. By contrast, growth of test strains of Streptococcus faecalis, S. faecium, saccharolytic C. botulinum types B, C, D, E and F and proteolytic strains of types C and D was suppressed on this medium, as were strains of 26 other spp. of clostridia. Addition of

50 .mu.g/ml of polymyxin to the agar medium had no detectable effect on the recovery of C. sporogenes or C. botulinum. When samples of soil and mud were plated on the antibiotic-containing medium, 63.1% of 225 isolates thus obtained were identified as C. sporogenes/botulinum.

AB Two selective media for the enrichment and qual. detn. of P. aeruginosa in pharmaceutical products are described. Besides the normal constituents, the solid media contain N-cocos-.beta.- propionic acid (1-3 g/l.) and a Cd salt (preferably CdSO4, 0.05-0.3 g/l.). The pH of the media was adjusted to 6.6-7.6 with the opt. at pH 7.2. The complete medium was autoclaved. The incubation period was 1-3 days at 35-39. The identification of distinct groups of P. aeruginosa was made using media addnl. contg. D,L- ***alanine*** for pyocyanine formation or glycerine and phosphate for prodn. of fluorescing compds.

AB Adams, James N. (University of South Dakota, Vermillion). Recombination between Nocardia erythropolis and Nocardia canicruria. J. Bacteriol. 88:865-876. 1964.-Nutritionally complementary auxotrophic mutants derived

from Nocardia erythropolis did not yield prototrophic recombinants when progeny from mixed cultures or newly mixed strains were inoculated onto minimal medium. Similarly, complementary auxotrophic mutants of N. canicruria did not produce prototrophic recombinants. When interspecific mating was attempted between complementary mutants of N. erythropolis and N. canicruria, prototrophic recombinants were recovered at frequencies dependent, in part, upon the auxotrophic strains used in the test crosses. Growth of the parental types in mixed cultures was necessary for the production of recombinant progeny. Direct selection for recombinants by inoculating the ***selective*** ***medium*** with a mixture of parental types without prior mixed growth did not result in the recovery of recombinants. Varying the medium upon which mixed growth occurred, or varying the ratio of N. erythropolis to N. canicruria cells used as inocula, did not greatly affect the recovery of recombinants. Heat-killing one or the other of the parental types prevented recombinant production. The lack of recovery of recombinants from crosses of homologously derived strains suggested that a mating factor controls recombination. The mating factor was not eliminated by acriflavine treatment. The recovery of a recombinant strain capable of forming recombinants with either N. erythropolis or N. canicruria, and the recovery of another strain which mated only with N. erythropolis in backcrosses, suggests that the mating factor may be of a multiple nature.

AB The ruminal selenomonad strain H18 grew rapidly (.mu. = 0.50 h-1) in a defined ***medium*** containing glucose, ammonia, purified ammonia acids, and sodium (95 mM); little if any ammonia was utilized as a nitrogen source. When the sodium salts were replaced by potassium salts (0.13 mM sodium), there was a small reduction in growth rate (.mu. = 0.34 h-1), and under these conditions > 95% of the cell nitrogen was derived from ammonia. No growth was observed when the ***medium*** lacked sodium (< 0.35 mM) and amino acids were the ***only*** ***nitrogen*** ***source*** . At least six amino acid transport systems (aspartate, glutamine, lysine, phenylalanine, ***serine*** , and valine) were sodium dependent, and these systems could be driven by an electrical potential (.DELTA..psi.) or a chemical gradient of sodium. H18 utilized lactase as an energy source for growth, but only when sodium and aspartate were added to the ***medium*** . Malate or fumarate was able to replace aspartate, and when these acids were added, sodium was no longer required. Glucose-grown cells accumulated large amounts of polysaccharide (64% of dry weight), and when the exogenous glucose was depleted, this material was converted to acetate and propionate as long as sodium was present. When the cells were incubated in buffers lacking sodium, succinate accumulated and exogenous succinate could not be decarboxylated. Because sodium had little effect on the transmembrane pH gradient at pH 6.7 to 4.5, it did not appear that sodium was required for intracellular pH regulation.
AB The ruminal selenomonad strain H18 grew rapidly (.mu. = 0.50 h-1) in a defined ***medium*** containing glucose, ammonia, purified ammonia acids, and sodium (95 mM); little if any ammonia was utilized as a nitrogen source.. . . and under these conditions > 95% of the cell nitrogen was derived from ammonia. No growth was observed when the ***medium*** lacked sodium (< 0.35 mM) and amino acids were the ***only*** ***nitrogen*** ***source*** . At least six amino acid transport systems (aspartate, glutamine, lysine, phenylalanine, ***serine*** , and valine) were sodium dependent, and these systems could be driven by an electrical potential (.DELTA..psi.) or a chemical gradient. . . sodium. H18 utilized lactase as an energy source for growth, but only when sodium and aspartate were added to the ***medium*** . Malate or fumarate was able to replace aspartate, and when these acids were added, sodium was no longer required. Glucose-grown. . .

AB A number of ***serine*** proteinases are secreted into the culture ***medium*** when Tritirachium album Limber is supplied with protein as the ***only*** ***nitrogen*** ***source*** . From this population of proteinases, we have isolated two novel proteolytic enzymes, designated as proteinase R and T. We have compared the thermal stability of these two proteinases with that of subtilisin BPN' and proteinase K. Both of these proteinases were thermally stable in the absence of detergents in buffers of low (4.0) and high (10.0) pH. The thermal stability of proteinase T was not affected by the presence of 1.0% SDS either at pH 8.0 or 10.0 in contrast to proteinase R which became heat labile. At low pH, the presence of SDS was detrimental to the stability of all the proteinases.

AB The presence on nutritive basal ***medium*** of L-amino acids (***alanine*** , asparagine, glycine, and proline) influenced the behaviour of Biscogniauxia mediterranea, a facultative nonaggressive parasite frequently isolated from healthy and declining oak trees. Larger

colony growth and dry weight of mycelium was observed on asparagine-enriched ***medium*** , while limited performance was shown by glycine-enriched ***medium*** . In contrast, a variable behaviour of the isolates was reported when ***alanine*** and proline were the ***only*** ***nitrogen*** ***source*** . In the attempt to correlate these results to the plant N-metabolism, the composition of free amino acids and their precursors were analysed in leaves of Quercus pubescens and Q. robur trees in Italy. Largely-variable distribution of individual amino acid concentration and of the aspartic acid/asparagine and glutamic acid/glutamine ratios was observed among healthy and declining oaks. Despite the in vitro results, it was not possible to apply the study to the amino acids as a distinctive marker for a stress condition in plants, especially in forest stands where many factors might influence the nitrogen plant metabolism.

AB The contribution of amino acids other than glutamine to renal ammoniagenesis was studied in renal tubules obtained from control rats and rats with metabolic acidosis by incubating 2.5 mM [5-15N]glutamine, [2-15N]glutamine, [15N]glutamate, [15N]aspartate, [15N] ***alanine*** or [15N]glycine, as the ***only*** ***nitrogen*** ***source*** in Krebs bicarbonate buffer or as a labelled substrate in a ***medium*** containing a mixture of unlabelled amino acids. With control tissue in Krebs buffer, about 75% of total ammonia was derived from 5-N of glutamine, whereas 2-N of glutamine, glutamate, aspartate, ***alanine*** and glycine supplied 1, 10, 13, 4 and 18%, respectively. In the acidotic state, these values were 51, 30, 30, 30, 10 and 15% of total ammonia produced, respectively. Ammonia that could not be accounted for by 15N analysis was derived from endogenous sources. Studies with tubules incubated in Krebs ***medium*** alone indicated that, in control and acidosis, the calculated fraction of ammonia derived from endogenous

sources was significantly decreased by addition of 0.7 or 2.5 mM glutamine. Ammonia production from endogenous sources was similar whether 0.7 or 2.5 mM glutamine was used as only exogenous substrate. Incubations of control tissue in buffer supplemented with an amino acid mixture revealed a decrease in ammonia production from [5-15N]glutamine compared with incubation in Krebs buffer alone. In chronic acidosis, no significant difference was found in total ammonia formation from [5-15N]glutamine compared with that in Krebs buffer alone. In control and acidosis, the fraction of NH3 derived from glutamate, aspartate, ***alanine*** or glycine was lower in the ***medium*** supplemented with amino acids than with that in Krebs buffer.

AB The proteolytic activity of Butyrivibrio fibrisolvens, a ubiquitously distributed bacterial species in the gastrointestinal tracts of ruminants and other mammals, was characterized. The relative proteolytic activity (azocasein degraded in [mu]g/h mg protein) varied greatly with the strain: 0 to 1 for strains D1, D16f, E21C, and X6C61; 7 to 15 for strains IL631, NOR37, S2, LM8/1B, and X10C34; and 90 to 590 for strains 12, 49 H17C, CF4c, CF3, CF1B, and R28. The activity levels of the last group of strains were equal to or greater than those found with Bacteroides amylophilus or Bacteroides ruminicola. With the exception of strain R28 activity, 90% or more of the proteolytic activity was associated with the culture fluid and not the cells. Strain 49 produced proteolytic activity constitutively, but the level of activity (units/mg protein) was modulated by growth parameters. With various carbohydrates added to the growth ***medium*** , the proteolytic activities of strain 49 were positively correlated with

the growth rate. When the growth rate varied with the use of different nitrogen sources, a similar correlation was not found. The highest activity was observed with Casamino Acids (1 g/litre), but this reduced by about 70% with Trypticase (BBL Microbiology Systems, Cockeysville, MD) or casein (1 g/litre) and by 85% with ammonium chloride (10 mM) as the ***only*** ***nitrogen*** ***source*** . The addition of ammonium chloride (1 to 10 mM) to media with low levels of Casamino Acids or Trypticase resulted in lower proteolytic activities but not as low as seen when the complex N sources were increased to 20 g/litre. Proteolytic activity was affected slightly if at all by freezing and increased proportionally with the assay temperature up to 47[deg]C. No precise optimum pH was observed, and the highest activities were in the pH range of 5.5 to 7.0. The proteolytic activity was insensitive to oxygen, and dithiothreitol or L-cysteine inhibited activity up to 40%. The effects of protease inhibitors indicated the proteolytic activities of the culture fluid and cells, which are the same and are of a ***serine*** protease type. Preliminary data from initial purification procedures suggest that the proteolytic activity in the culture fluid consists of a low-molecular-weight protein that is associated with carbohydrate material.

AB In NMR spectra of complex proteins, sparse isotope enrichment can be important, in that the removal of many 13C-13C homonuclear J-couplings can narrow the lines and thereby facilitate the process of spectral assignment and structure elucidation. We present a simple scheme for selective yet extensive isotopic enrichment applicable for prodn. of proteins in organisms utilizing the Entner-Doudoroff (ED) metabolic pathway. An enrichment scheme so derived is demonstrated in the context of a magic-angle spinning solid-state NMR (MAS SSNMR) study of Pf1 bacteriophage, the host of which is Pseudomonas aeruginosa, strain K

(PAK), an organism that uses the ED pathway for glucose catabolism. The intact and infectious Pf1 phage in this study was produced by infected PAK cells grown on a minimal ***medium*** contg. 1-13C -glucose (13C in position 1) as the sole carbon source, as well as 15NH4Cl as the ***only*** ***nitrogen*** ***source*** . The 37 MDa Pf1 phage consists of about 93% major coat protein, 1% minor coat proteins, and 6% single-stranded, circular DNA. As a consequence of this compn. and the enrichment scheme, the resonances in the MAS SSNMR spectra of the Pf1 sample were almost exclusively due to carbonyl carbons in the major coat protein. Moreover, 3D heteronuclear NCOCX correlation expts. also show that the amino acids leucine, ***serine*** , glycine, and tyrosine were not isotopically enriched in their carbonyl positions (although most other amino acids were), which is as expected based upon considerations of the ED metabolic pathway. 3D NCOCX NMR data and 2D 15N-15N data provided strong verification of many previous assignments of 15N amide and 13C carbonyl shifts in this highly congested spectrum. Both the semi-selective enrichment patterns and the narrowed linewidths allowed for greater certainty in the assignments as compared with use of uniformly enriched samples alone.

AB Centaurea calcitrapa hairy root cultures were established by infection with Agrobacterium rhizogenes strain LBA 9402. The liq. ***medium*** hairy root cultures exhibited a biomass doubling time of approx. 1.5 days in the 20 days exponential growth phase. The effect of the initial

sucrose and nitrogen concns. in biomass and proteinase prodn. of the liq. ***medium*** cultures was studied. The highest values for both proteolytic activity and fresh wt. were attained between 30 and 50 g/L sucrose. A low ammonium/nitrate ratio favored the development of hairy roots and proteolytic activity. The best results for both parameters in terms of nitrogen nutrition were obtained with nitrate (24.7 mM) as the ***only*** ***nitrogen*** ***source*** . The max. proteolytic activity was found to be at pH 4.0, within the pH range for aspartic proteinases (APs), and the inhibition studies showed that only pepstatin A, specific for that class of enzymes, revealed a significant inhibitory effect. The C. calcitrapa aspartic proteinase (cenprosin) gene was detected in hairy roots using specific PCR primers. The specific proteolytic activity present in hairy roots seems to be lower than the reported for flowers, but similar to the existent in the untransformed roots and cell suspension cultures.
